Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description**BACKGROUND OF THE INVENTION****5 1. Field of the Invention**

This invention relates to transport vectors for targeting drugs to cells *in vitro* and to tissues *in vivo*. In particular, this invention relates to targeting vectors based on avidin-biotin technology for delivery of peptides and oligonucleotides to cells and tissues *in vivo* and *in vitro*. The invention further concerns soluble transport vectors that are comprised of avidin fusion proteins which mediate cellular uptake of biotinylated oligonucleotides and peptides, as well as avidin protection of circulating oligonucleotides from serum 3'-exonucleases.

2. Description of Related Art

15 The publications and other reference materials referred to herein to describe the background of the invention and to provide additional detail regarding its practice are hereby incorporated by reference. For convenience, the reference materials are numerically referenced and grouped in the appended bibliography.

20 Antisense oligonucleotides are potentially highly specific chemotherapeutic agents for the treatment of cancer, viral infections, and other disorders (1). There are two principal obstacles to effective delivery of antisense oligonucleotides to tissues: (a) poor transport of oligonucleotides across cell membranes, and (b) rapid degradation by tissue and serum nucleases. The minimal cellular uptake of the highly charged oligonucleotide compounds has been dealt with by adding to cells in tissue culture concentrations of antisense oligonucleotides ranging from 10 to 100 μ M to achieve biological effects (3). Prohibitively higher concentrations will be required *in vivo* where capillary barriers retard the delivery of oligonucleotides to cells.

25 The nuclease problem has been dealt with by synthetic preparations of phosphorothioate nucleic acid derivatives (4). However, these nucleic acids require the use of unnatural nucleotides and thus cannot be prepared by recombinant DNA technology. The necessity for organic synthesis of the phosphorothioate oligonucleotide may significantly limit the industrial scale production of such compounds.

30 Liposomes have been used to deliver antisense oligonucleotides to tissues *in vitro*, in particular where capillary barriers are absent (5). However, liposomes are not effective delivery vehicles *in vivo* because they selectively deliver the drug to macrophages lining the reticuloendothelial system, and because they are too large to effectively cross capillary barriers *in vivo* (6). In particular, liposomes have not proven to be effective drug delivery vehicles for transport into brain across the brain capillary barrier system, i.e., the blood brain barrier (BBB) (7).

35 Recognizing this problem, other investigators have prepared polylysine conjugates with vector proteins such as asialofetuin, which is taken up by receptor mediated endocytosis into liver cells, or transferrin, which is taken up by organs expressing high quantities of transferrin receptor on the cell membrane (8, 9). The limitations of this approach are two-fold.

40 First, the asialofetuin- or transferrin-polylysine conjugate must be prepared chemically, oftentimes with low yields. Secondly, the interaction between the polylysine and the antisense oligonucleotide is not covalent and subject to rapid dissociation *in vivo*. Therefore, it would be advantageous to conjugate the antisense oligonucleotide to the transport vector via a high affinity bond that is stable in circulation but is labile in tissues.

45 It would be desirable to eliminate the need to couple the DNA binding protein to a vector compound. It would also be desirable if the targeting molecule to which the nucleotide binds would be stable in the circulation *in vivo*. It would be further desirable if such a targeted oligonucleotide was resistant to serum nucleases, thereby avoiding the need to use synthetic and unnatural oligonucleotides in preparation of antisense derivatives.

50 Current peptide delivery to tissues entails the use of liposomes (10), which have the limitation described above, and the preparation of chimeric peptides (11). The latter involves covalent conjugation, generally using disulfide bonds, of the pharmaceutical peptide to its transport vector. This often involves complex linker chemistry. It would be desirable if peptide drug delivery could be achieved with simpler linker chemistry to yield linkage of a peptide to a transport vector, the linkage being of high affinity and in high yield. It would be further desirable if the link between the peptide and transport vector would be stable in plasma and labile in cells.

55 Peptide delivery to tissues *in vivo* involves the formation of chimeric peptides by covalent bonding of peptides to transport vectors. (11) The complex linker chemistry involved in the formation of chimeric peptides often produces low chemical yields which may not be optimal for industrial-scale production. It would be desirable to have linker chemistry in peptide delivery that is simple, associated with high yields and may be applied to industrial-scale production.

Accordingly, further developments are needed to make available a conjugation chemistry that would allow for tight binding of a drug, such as an oligonucleotide or peptide, to a transport vector within the circulation. It would be desirable to eliminate linker chemistry that involves covalent attachment of oligonucleotide or peptide drug to a tissue specific transport vector (12). Further desired would be a linker technology for drug delivery which provides the advantages of

stability in plasma, lability in tissues, and high efficiency of drug/vector coupling that is necessary for industrial-scale production of chimeric peptides or oligonucleotides.

EP-A-0251494 discloses a two-stage method of drug sequestration comprising further administering an avidin-containing binding protein and allowing it to localise at a target site for typically 1 to 4 days. Circulating binding protein is then cleared from the bloodstream using a clearing agent. A biotinylated agent is then administered to localise the agent at the target site.

In accordance with the present invention, a composition is provided for delivering an agent to cells *in vitro*, or to cells within tissues or organs *in vivo*. The composition comprises a transport vector comprising an avidin moiety chosen from avidin tetramer, avidin monomer subunit, avidin dimer subunit, and non-glycosylated derivatives thereof;

at least one monobiotinylated agent bonded to said avidin moiety via an avidin-biotin linkage to provide an avidin-biotin-agent complex.

Further provided is a method for delivering an agent to cells *in vitro* using the composition of the present invention, which composition comprises the transport vector bonded to the monobiotinylated agent. The method includes contacting cells with the composition. The composition comprises an avidin moiety chosen from avidin tetramer, avidin monomer subunit, avidin dimer subunit or non-glycosylated derivatives thereof as a transport vector bonded to a monobiotinylated agent to form an avidin-biotin-agent complex.

The invention further provides a composition comprising the avidin-biotin-agent complex described for use in delivering an agent to cells, wherein said cells comprise tissues and organs *in vivo*. Such a use may include administering a therapeutic dosage to a subject of a pharmaceutical composition comprising the avidin-biotin-agent complex in a pharmaceutically-acceptable carrier.

It may also include administering a diagnostic treatment to a subject which involves administering to the subject an appropriate amount of the avidin-biotin-agent complex, wherein the agent is a diagnostic compound.

Further, a method is provided for synthesizing the avidin-biotin-agent complex. The method involves forming a transport vector, forming a monobiotinylated agent, and bonding the transport vector to the monobiotinylated agent via an avidin-biotin linkage to form an avidin-biotin-agent complex.

As pointed out above, the composition for delivering an agent to a cell comprises a transport vector bonded via an avidin-biotin linkage to a monobiotinylated agent to provide an avidin-biotin-agent complex. The transport vector includes an avidin moiety. The transport vector may further include a targeting moiety bound to the avidin moiety. The targeting moiety provides targeted transport of the avidin-biotin-agent complex to specific cells.

The present invention further envisions the transport vector as a substantially purified, fused polypeptide produced from a fused gene encoding nucleotide sequences encoding the avidin moiety and the targeting moiety. The invention further concerns itself with DNA sequences or DNA constructs, host cells, and recombinant methods for producing the fused polypeptide targeting vector.

The present invention provides useful advantages for delivery of antisense oligonucleotides to tissues in four respects. First, the cationic nature of avidin allows avidin to directly target cells, and eliminates the need to couple the cationic protein, such as polylysine to the targeting moiety, e.g., transferrin or asialo-glycoproteins by complex methods well known in the art (8, 9). Second, the high affinity nature of the avidin-biotin bond provides advantages of the present invention over well known methods for delivery of antisense oligonucleotides to tissues (8, 9) which rely on the low affinity interaction between the negative phosphate charges on nucleic acid molecules and the positive charges on the poly-lysine coupled to the transport vector. Third, the use of the avidin-biotin technology in the present invention eliminates the frequent need for complex methods of coupling between the polycationic protein (e.g., polylysine) and the transport vector (e.g., transferrin). The function of both of these proteins (i.e., transferrin and polylysine) are found together in the avidin molecule's cationic nature, which triggers absorptive-mediated endocytosis into cells, and in the avidin molecule's high affinity binding of biotin. Fourth, the 3' biotinylation of antisense oligonucleotides allows for avidin protection against 3' exonucleases in serum. This latter advantage is the basis for the method of the present invention which involves protecting oligonucleotides from 3' exonuclease degradation. By monobiotinylating an oligonucleotide toward the 3' end and reacting the monobiotinylated oligonucleotide with an avidin moiety, an avidin-biotin-oligonucleotide complex is formed which is resistant to 3' exonuclease degradation in serum.

The present invention also presents advantages in light of the well known methods of peptide delivery to tissues *in vivo*. Presently, peptide delivery involves the covalent coupling of peptides to their transport vectors in the formation of a chimeric peptide (16). The linker chemistry involved in the formation of chimeric peptides is usually complex and is at times associated with low chemical yield that may not be optimal for industrial scale production. Conversely, the chemistry of the present invention involved in monobiotinylation of peptides is simple, associated with high yields, and may be applied to industrial scale production.

The above discussed and many other features and attendant advantages of the present invention will become better understood by reference to the following detailed description of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1a, 1b, and 1c refer to protecting oligonucleotides from exonuclease degradation by biotinylation of the oligonucleotide near the 3' end; Fig. 1a shows a 21-mer antisense oligonucleotide with a biotin placed toward the 3' end; Fig. 1b shows an autoradiogram of a gel demonstrating avidin's prolonging effect on the stability of biotinylated oligonucleotides in serum; Fig. 1c, shows a quantitation of the autoradiogram of portion Fig. 1b indicating avidin protecting the biotinylated oligonucleotide against degradation by 3' exonuclease in serum.

Fig. 2 is a diagram of an avidin fusion gene and avidin fusion protein of the present invention showing avidin linked to a tissue specific monoclonal antibody (immunoglobulin).

DETAILED DESCRIPTION OF THE INVENTION

The invention provides a composition for delivering an agent to cells, the composition including a transport vector bonded to a monobiotinylated agent through an avidin-biotin linkage to provide an avidin-biotin-agent complex.

The transport vector of the present invention comprises an avidin moiety chosen from avidin tetramer, avidin monomer subunit, avidin dimer subunit, and non-glycosylated derivatives thereof. The targeting moiety is useful for making the avidin-biotin agent complex more targetable, that is, better aimed than an avidin-biotin agent complex without a targeting moiety. By more targetable is meant that such targeting moieties have higher affinities for a more restricted range of tissues and organs. The targeting moieties of the present invention are selected from the group consisting of receptor ligands, such as but not restricted to insulin and transferrin, anti-receptor monoclonal antibodies, cationized proteins, and lectins.

The transport vector can be a fusion polypeptide comprised of an amino acid sequence for avidin (20) fused to an amino acid sequence representing a targeting moiety. The fusion polypeptides that make up the transport vector can be produced from a fused gene. Exemplary gene fusion systems for making the fusion polypeptides include a fusion gene sequence involving a construct between a DNA sequence encoding avidin and a DNA sequence encoding the constant and variable regions of an immunoglobulin. See Figure 2. The gene structures encoding immunoglobulins are well known as are the methods for making fusion gene sequences or constructs between various portions of immunoglobulin genes and other genes. Employing these methods, the exons encoding the heavy chain genes, C_H2 and C_H3, are replaced by exons corresponding to the avidin gene. The avidin moiety is linked to the truncated immunoglobulin at the F_c region. This fusion gene, along with genes encoding light chain variable and constant regions, may then be inserted in a variety of commonly used vector such as pPROK-1 (Clontech Laboratories, Palo Alto, California) for a prokaryotic expression system or pMAM_{neo} (Clontech Laboratories) or pSVL SV40 (Pharmacia, Piscataway, New Jersey) for eukaryotic expression systems. The fused gene has a nucleotide sequence encoding the fused polypeptide, and is comprised of a nucleotide sequence encoding the avidin moiety fused to a nucleotide sequence encoding the targeting moiety. Preferably, the nucleotide sequence that encodes the dimer subunit of avidin is used. A typical DNA sequence or construct encoding the fusion polypeptide of avidin and immunoglobulin variable region is schematized in Figure 2, and incorporates sequences in reference no. 20 and in U.S. Patent NO. 4,839,293.

The present invention includes recombinant host cells containing DNA sequences, including those encoding the fusion polypeptide having the structure shown in Figure 2. The recombinant host cell produces the fusion polypeptide in a sufficient quantity for a substantial isolation and purification of the fusion polypeptide. The fusion polypeptide itself is included in the present invention as well as compositions comprising the fusion polypeptide. Well known methods in the art are used for synthesizing recombinant fused proteins. (24) Typical recombinant host cells for producing the fusion polypeptide include eukaryotic cells, such as human embryonic kidney cells, and prokaryotic cells, such as E. coli.

Avidin is a cationic protein with an isoelectric point (pI) of 10, (13) owing to a preponderance of basic amino acids (lysine, arginine) relative to acidic amino acids (aspartic acid, glutamic acid) (13). In contrast, the bacterial homologue of avidin, called streptavidin, which is 38% homologous with avidin, is a slightly acidic protein with a pI of 5 to 6 (15). Like avidin, streptavidin binds biotin with extremely high affinity (15).

It has been shown that avidin is taken up by tissues, such as brain, liver, and kidney by an absorptive-mediated endocytosis mechanism observed for other cationic proteins, such as histone or cationized albumin. (16, 17) This property of avidin can, if desired, eliminate the need for coupling avidin to a separate transport vector.

The protein avidin, as shown in the present invention, is a vector for the transportation to cells *in vivo* or *in vitro* of biotinylated agents, and has two features making it particularly suitable for drug delivery: (a) avidin is cationic, a property determined by the present inventors which allows avidin to undergo absorptive-mediated endocytosis into cells *in vivo* or *in vitro*, and absorptive-mediated transcytosis across microvascular barriers *in vivo*; and (b) avidin has a high affinity binding site for the water-soluble vitamin biotin. Biotin is a molecule that can be easily conjugated to oligonucleotides or peptides.

The avidin-biotin bond is one of the highest affinity binding reactions found in nature with a molar dissociation constant of 10⁻¹⁵M (13), and a t_{1/2} of ligand dissociation of 89 days (13). The avidin-biotin bond is stable in serum and in

the circulation (18), but it is broken at the tissue site (18), where the drug may be released to produce pharmacological activity.

Avidin is a 64,000 dalton homotetramer glycoprotein (13), and has been administered to humans in large concentrations without untoward effects (19). Each 16,000 monomer of avidin contains a high-affinity binding site for the water-soluble vitamin biotin and the avidin tetramer binds four biotin molecules (13). The avidin gene cDNA has been cloned (20), and avidin can be produced in industrial-scale quantities using recombinant DNA technology.

The simple addition to avidin of biotinylated nucleic acids, or biotinylated peptide pharmaceuticals, results in the high affinity and direct action of the avidin moiety with the oligonucleotides or peptide pharmaceutical.

Biotinylated nucleic acids may be prepared chemically, by inserting an amino nucleotide at one end of the nucleic acid, or by recombinant DNA technology, employing a biotinylated nucleotide substrate. *E. coli* DNA polymerase recognizes biotinylated nucleotides (21). The avidin cDNA has been cloned (20), and the preparation of fusion proteins, wherein avidin is genetically fused to an organ-specific vector (see Figure 2) may eliminate the rapid clearance of avidin from blood. This approach may also provide a strategy for industrial-scale production of avidin chimeric peptides that are suitable for delivery of biotinylated antisense oligonucleotides or peptides to tissues *in vivo*.

Peptides may be biotinylated chemically, using activated biotin analogues, such as N-hydroxysuccinimidobiotin (NHS-biotin), which is commercially available from Pierce Chemical Company, Rockford, IL and requires the presence of a free primary amino group on the peptide. Moreover, peptides and proteins produced by recombinant DNA technology may be biotinylated in industrial quantities by preparing fusion genes that encode for an approximately 75 amino acid consensus sequence that allows for biotinylation of a lysine residue by *E. coli* biotin ligase, which results in the bacterial secretion of biotinylated protein (22).

Therefore, biotinylated peptides and proteins, biotinylated oligonucleotides, and avidin may all be produced by recombinant DNA technology.

It should be noted that, although avidin is 10% glycosylated, the non-glycosylated avidin still binds biotin with equally high affinity (23). Therefore, non-glycosylated avidin produced in bacterial expression systems, in accordance with the present invention, is preferred for pharmaceutical purposes.

The avidin moiety of the present invention can be the monomer subunit of avidin, the dimer subunit, or the tetramer. Either the glycosylated- or non-glycosylated derivatives of the avidin monomer, dimer, or tetramer may be used. Use of the avidin oligomer is preferred because the affinity of the monomer for biotin is much less than the affinity for biotin of the oligomer (14). The monobiotinylated agent of the present invention is bonded to the avidin moiety of the transport vector via an avidin-biotin linkage. The molecule formed by this linkage is referred to in this description as an avidin-biotin-agent complex.

The invention concerns at least one monobiotinylated agent bonded through an avidin-biotin linkage to a transport vector. The agent is monobiotinylated to avoid the formation of aggregates which might be insoluble or rapidly removed by liver function or by the reticuloendothelial system.

According to the present invention, an agent to be monobiotinylated for delivery to cells is selected from the group consisting of oligonucleotides, polypeptides, immunoglobulins, and organic chemicals.

As described below in Example 3, the monobiotinylated agent moiety can be an oligonucleotide which is monobiotinylated at the 3' end of the oligonucleotide. This provides the advantage of preventing degradation of the monobiotinylated oligonucleotide in serum by 3' exonucleases. The oligonucleotide can be an antisense oligonucleotide. Typical antisense oligonucleotides which can be used in the composition of the present invention include those complementary to the mRNA corresponding to oncogene products, viral-specific proteins, enzymes, transporter proteins, or other peptides and oligonucleotides vital to normal or pathologic cellular function.

According to the invention, a method is provided for protecting oligonucleotides from 3' exonuclease degradation in serum and from 3' exonuclease degradation in tissues where they may be present. (See Example 3, below) The method for protecting oligonucleotides from 3' exonuclease degradation involves the step of monobiotinylating the oligonucleotide to form a biotinylated oligonucleotide. The site of biotinylation is toward the 3' end of the oligonucleotide. The method reacts the monobiotinylated oligonucleotide with an avidin moiety to form an avidin-biotin-oligonucleotide complex, protecting the oligonucleotide from 3' exonuclease degradation upon administration to an individual or to cells *in vitro* where exonucleases may be present.

The agent which is monobiotinylated according to the method of the present invention can be a pharmaceutical compound selected from the group consisting of but not restricted to methotrexate, amphotericin, catecholamines, or peptides. Amphotericin is useful in treating brain fungal diseases, catecholamines useful for treating depression or Parkinson's disease.

Agents which are diagnostic compounds can be monobiotinylated for use in the invention. Such diagnostic compounds can be selected from the group consisting of, but not restricted to oligonucleotides, immunoglobulins, amyloid ligands, and receptor ligands. Receptor ligands which are monobiotinylated in the present invention are not restricted to peptides, catecholamines, or steroid hormones. Typical diagnostic procedures in which these compounds are employed include, but are not restricted to, search for tumors, amyloid, abscess, or auto-immun reactions. For example, amyloids are proteinaceous, gel-like deposits that are formed in disease processes, such as Alzheimer's Disease. Amy-

Ioids have a special binding affinity for certain proteins in the blood, such that when the protein comes in contact with the amyloid, the protein will stick to it. Those proteins can be tagged with radioactivity. When these tagged proteins bind to the amyloid, it is possible to image the pattern of binding and observe a condition such as Alzheimer's Disease.

5 In accordance with the present invention, a pharmaceutical composition is provided which includes the composition of the present invention in a pharmaceutically-acceptable carrier. Suitable pharmaceutical carriers are selected on the basis of the nature of the avidin moiety, the monobiotinylated agent comprising the avidin-biotin-agent complex, the presence of the targeting moiety linked to the transport vector, the targeted cells *in vivo* (issue/organ) or *in vitro*, and the particular use -- therapeutic, diagnostic, or otherwise. For example, a suitable pharmaceutical carrier for the avidin-biotin-agent complex consisting of avidin-biotinylated oligonucleotide is normal saline, as illustrated in Example 1, below. Other suitable pharmaceutical carriers for particular uses are saline solutions containing dilute detergents.

10 The avidin-biotin-agent complex of the present invention is useful in delivery of the agent to cells. These cells are organs and tissues within an animal. A method for delivering an agent to organs and tissues within an animal involves the step of administering the avidin-biotin-agent complex to the subject. Further, the avidin-biotin-agent complex is useful for delivery of an agent to cells located *in vitro*. For example, cell cultures in dishes or flasks are delivery targets for 15 the transport vector linked to the monobiotinylated agent according to the present invention. In the appropriate carrier, the avidin-biotin-agent complex is added to the medium in which cells are growing *in vitro* and thereby the invention achieves contacting those cells with the transport vector and the delivery of the avidin-biotin-agent complex to the cells. Appropriate carriers include normal saline or tissue culture medium.

15 The avidin-biotin-agent complexes in accordance with the present invention are well-suited for delivering an agent to cells both *in vivo* or *in vitro*. A first step of the method provides a composition which includes a transport vector linked to a monobiotinylated agent through an avidin-biotin linkage to provide an avidin-biotin agent complex. The transport vector linked to the monobiotinylated agent may further include a targeting moiety. The targeting moiety provides targeted transport of the avidin-biotin-agent complex to specific cells. The second step of the method is contacting the cells with this composition. The cells include tissues and organs *in vivo* and cells *in vitro*.

20 25 The method delivers an agent to tissues and organs *in vivo* such as the brain, liver, kidney, lung, or heart. A composition having the avidin-biotin-agent complex is administered to an individual in a pharmaceutically-acceptable carrier. Methods for administering the avidin-biotin-agent complex to individuals involve administering a therapeutic dosage to the subject. A therapeutic dosage can be from about .001 milligrams per kilogram to about 1 milligram per kilogram.

30 35 The invention further includes a method for administering a diagnostic treatment to a subject, which involves administering to the subject an appropriate amount of the avidin-biotin-agent complex. In this diagnostic complex, the agent can be a specific monoclonal antibody that is labeled with either an isotope or an appropriate contrast agent. Such treatments would be used for the purpose of diagnosing the presence of cancer, various autoimmune diseases, such as multiple sclerosis, or other conditions involving brain abscesses and neurodegenerative conditions, such as 40 Alzheimer's disease.

35 According to the invention, the avidin-biotin-agent complex may be prepared in a number of different ways. The steps of the methods involve forming a transport vector, the transport vector having an avidin moiety selected from the group consisting of the avidin tetramer, the avidin dimer, and the avidin monomer subunit. Glycosylated and non-glycosylated derivatives of the avidin can be used in the present invention. Another step is to form a monobiotinylated agent. 40 Avidin-biotin-agent complexes are formed by makings a bond between the avidin of the transport vector and the biotin of the monobiotinylated agent to provide an avidin-biotin linkage and a stable avidin-biotin-agent complex. The transport vector can also include a targeting moiety bound to the avidin moiety. The transport vector can be synthesized by recombinant means, as well.

45 The following examples are offered by way of illustration.

Example 1

Avidin-Biotin Soluble Transport Vector

50 This example demonstrates that the avidin-biotin system of the present invention is capable of mediating specific cellular uptake of biotinylated antisense oligonucleotides or peptides to cells *in vitro* and tissues *in vivo*.

The model antisense oligonucleotides used in these studies was a 21-mer complementary to the bovine GLUT-1 glucose transporter mRNA (2) and corresponds to nucleotides -9 to +12 (where +1 corresponds to the first nucleotide of the methionine initiation codon) and the thymine base at +10 of the mRNA is replaced by 6-amino uracil suitable for biotinylation within NHS-biotin near the five prime end of the antisense oligonucleotide, (see Formula I, below).

Formula I [avidin] • (biotin)-(CH₂)₄CONH-[DNA]

An extended primary amine group was added to the antisense oligonucleotide by replacing the deoxythymidine at position 3, with 6-aminodeoxyuridine (aU) (Genosys Biotechnologies, Inc., The Woodlands, Texas), yielding the following oligonucleotide, 5'-GGaUGGGCTCCATGGCCGCGCT-3'. The oligonucleotide was biotinylated by adding 73 nmol

of NHS-biotin (Pierce Chemical Co., Rockford, Illinois) to 6.9 nmol of amino-modified antisense oligonucleotide in 0.125 M NaHCO₃ at pH = 9. Following biotinylation, the product was purified by Sephadex G-25 gel filtration and labeled at the 5' end with polynucleotide T₄ kinase using [γ -P³²]-ATP, and this labeling resulted in a final product with a specific activity of 2.6 microcuries/pmol. The labeled oligonucleotide was repurified through a Sephadex G25 column, avidin 5 was added, and the avidin-biotin DNA complex was purified by Sephadex G75 column chromatography prior to all experiments.

The model peptide employed in this study was [desamino-Cys¹, D-Lys⁸] lysine vasopressin (DDLVP). Both *in vitro* and *in vivo* delivery of biotinylated DDLVP and biotinylated GLUT-1 antisense oligonucleotide were achieved.

Two different types of biotin analogues were employed in these studies. The GLUT-1 antisense oligonucleotide was 10 biotinylated with N-hydroxysuccinimidobiotin (NHS-biotin), [P³²]-labeled at the five prime end to form [P³²] bio-DNA. The NHS-biotin was obtained from Pierce Chemical Company, Rockford, IL. This biotinylation reaction resulted in the formation of an avidin-biotin bond that was resistant to thiol cleavage. The DDLVP was iodinated and then biotinylated 15 with a cleavable biotin linker employing sulfo-succinimidyl-2-(biotinamido) ethyl-1, 3-dithiopropionate (NHS-SS-biotin) to form [¹²⁵I]-bio-SS-DDLVP. This resulted in the formation of a disulfide-based linker and allows for thiol-based cleavage of the biotinylated drug from the avidin vector (21).

The DDLVP was synthesized by peninsula Laboratories in Belmont, California and was purified to homogeneity by C18 reverse phase high performance liquid chromatography and was radio labeled with ¹²⁵I iodine and chloramine T, followed by purification through a C18 Sep Pak extraction cartridge. A ten-fold molar excess of NHS-SS-biotin (Pierce Chemical Co., Rockford, Illinois) was added to 10 nmol of ¹²⁵I-DDLVP and 2 ml of 0.125 M NaHCO₃ (pH = 9), and following biotinylation, the excess reagents were removed as follows: 1 ml of 2.5 mg per milliliter of avidin was added in PBS (0.05 M Na₂HPO₄, 0.15 M NaCl, pH = 7.4), and after incubation for 90 minutes at 23° C, 2 ml of cold 0.025% neutral-dextran 80 (Sigma Chemical Co., St. Louis, Missouri) and 0.25% activated charcoal in Ringers solution (10 mM Hepes, pH = 7.4) was added while mixing, incubated 5 minutes at 4° C, and centrifuged at 10,000 g for 5 minutes at 4° C. The supernatant was clarified by filtration through an 0.22 μ Millex GV filter (Millipore Corporation, Bedford, Massachusetts) and stored at -20° C. In the absence of avidin, the labeled DDLVP was entirely depleted by the dextran-coated charcoal separation, but in the presence of avidin, the biotinylated ¹²⁵I DDLVP remained in the final supernatant.

The *in vitro* studies were performed with isolated bovine brain capillaries used as an *in vitro* model of blood brain barrier (BBB) transport (16). The findings demonstrated avidin-mediated uptake of biotin, biotinylated peptide, and biotinylated antisense oligonucleotide by isolated bovine brain capillaries *in-vitro*.

30 In particular, it was found that brain capillary preparations preferably took up [H^3]-biotin, [¹²⁵I]-bio-SS-DDLVP, or [P³²]-bio-DNA coupled to avidin whereas minimal uptake was observed without the avidin transport vector.

A control study indicated that the uptake of the biotin is approximately 4-fold greater than the uptake of avidin, consistent with 4 biotin binding sites per avidin tetramer (13).

35 The brain capillary uptake of [H^3]-biotin was found to be negligible in the presence of buffer (Ringer's buffer, 10 mM Hepes Buffer, pH=7.4) alone. However, when avidin was added to incubation, the brain capillaries avidly took up [H^3]-biotin. In contrast, the addition of 500 nM of streptavidin to the incubation mixture resulted in no increased uptake of the biotin. In this Example, streptavidin acted as an important control. This bacterial homologue of avidin is 38% homologous with avidin (26), has a similar size and molecular structure, but differs from avidin by having a slightly acidic pI of 5 to 6 (15).

40 The differences between the cationic avidin and the slightly acidic streptavidin underscored the importance of the cationic nature of avidin, which initiated the absorptive-mediated endocytosis of the avidin-biotin complex by brain capillaries.

Similar to other cationic proteins, such as cationized albumin or histone (16, 17), the absorptive-mediated endocytosis of avidin by isolated brain capillaries is competitively inhibited by the polycationic protein, salmon protamine (Sigma grade 4), with a Ki = 5 μ g per ml protamine (data not shown).

45 Another finding indicated that uptake was mediated by the cationic nature of avidin, not the attached carbohydrate. 50 mM α - methylmannoside (α MM) resulted in no significant inhibition of the uptake of the avidin-biotin complex by brain capillaries *in vitro*. These findings showed that the mannose-rich carbohydrate moiety of avidin does not trigger the saturable uptake of avidin by isolated brain capillaries (27).

50 The uptake by brain capillaries of [¹²⁵I]-bio-SS-DDLVP (0.5 μ Ci/ml, specific activity = 190 μ Ci/ μ g) was found to be negligible in the presence of Ringer's buffer, but was markedly increased in the presence of 500 nM avidin. In contrast, the pretreatment of the [¹²⁵I]-bio-SS-DDLVP-avidin complex with dithiothreitol (DTT) prior to addition to the isolated brain capillary brain preparation resulted in a marked decrease in the capillary uptake of the (¹²⁵I)-DDLVP peptide. The decreased uptake caused by the DTT treatment was due to cleavage of the disulphide bond, which separated the biotinylated DDLVP peptide from the avidin vector, as in Formula II, below.

Formula II

5

DTT

10 +

15

The uptake of [P^{32}]-bio-antisense oligonucleotide by isolated brain capillaries was relatively low and the subtake was greatly increased by the addition of 800 nM avidin to the incubation mixture. Conversely, there was no significant increase in uptake when 800 nM streptavidin was added to the incubation mixture.

20 The modest uptake of radioactivity in the presence of buffer alone represents uptake of [P^{32}] nucleotide or phosphate ion generated by capillary nuclease or phosphatase degradation of the antisense oligonucleotide. All incubations were performed at 23°C for thirty minutes with brain capillary (about 100 µg protein per flask).

In vivo

25 To demonstrate *in vivo* uptake, [H^3]-biotin/unlabeled streptavidin and [I^{125}]-avidin were co-injected intravenously into anaesthetized male Sprague-Dawley rats (250 - 300 grams) and serum radioactivity was measured for up to two hours after injection as DPM/ml as a percent of injected dose (17). The [H^3] biotin radioactivity data was fit to a monoexponential decay function using a non linear regression analysis to yield the intercept and slope (K) of the clearance curve. The half-time of clearance was calculated from K. The serum trichloroacetic acid (TCA) precipitable [I^{125}]-avidin 30 radioactivity data was fit to a biexponential clearance function as described previously (17). The intercepts and slopes of the clearance curves were used to compute the integral of serum radioactivity at each respective time point, and these integrals were used to calculate the volume of distribution (V_D) values (17). For other findings, [H^3]-biotin was similarly co-injected with an excess of unlabeled avidin and organ V_D values were computed.

35 Another *in vivo* example was performed in a parallel fashion to the *in vitro* study reported above. The findings demonstrated the avidin-mediated tissue uptake of [H^3]-biotin, avidin-mediated tissue uptake of [I^{125}]-bio-SS-DDLVP, and enhanced *in vivo* avidin-mediated tissue uptake of [P^{32}]-bio-antisense oligonucleotide.

40 Groups of rats were administered [H^3]-biotin along with unlabeled streptavidin and [I^{125}]-avidin and the rate of clearance of [H^3]-biotin or the [I^{125}]-avidin from serum was measured over a two-hour period. The [H^3]-biotin coupled to an excess of streptavidin was cleared relatively slowly with a half time of 2.4 ± 0.2 hours. Conversely, the [I^{125}]-avidin was cleared rapidly in a biexponential mechanism characterized by half times of 22 ± 13 seconds and 53 ± 6 minutes. In other experiments, [H^3]-biotin was injected with excess quantities of unlabeled avidin and the rate of clearance of the [H^3]-biotin from blood in these experiments paralleled that for the [I^{125}]-avidin.

45 In these studies, [H^3]-biotin/unlabeled streptavidin and [I^{125}]-avidin were intravenously co-injected into anesthetized male Sprague-Dawley rats (250-300g) and serum radioactivity was measured for up to 2 hours after injection as DPM/ml as a percent of injected dose (29). The [H^3]-biotin radioactivity was fit to a monoexponential decay function using a non-linear regression analysis to yield the intercept and slope of the clearance curve. The half-time was calculated from $\ln 2/\text{slope}$ of the clearance curve. The serum trichloroacetic (TCA) precipitable [I^{125}]-avidin radioactivity data was fit to a biexponential clearance function (29) to yield the intercepts and slopes of the two components of clearance. The intercepts and slopes of the clearance curves were used to compute the integral of serum radioactivity at each respective time point, and these integrals were used to calculate the volume of distribution, V_D .

55 The integrals of the plasma radioactivity for either the experiments involving the injection of [H^3]-biotin-streptavidin or [H^3]-biotin-avidin were computed from a pharmaco-kinetic analysis (17) of the findings. These integrals of plasma radioactivity were used to compute the organ volume of distribution (V_D) of H^3 -biotin in brain, liver, kidney, heart, and lung.

55 The findings demonstrated that the rapid clearance of the avidin-biotin complex from blood was due to uptake by liver and kidney, and that 10-20 times more biotin was delivered to the liver and kidney at 5 minutes after a single intravenous injection when the [H^3]-biotin was co-injected with avidin, as compared to the streptavidin co-injection.

The liver and kidney biotin V_D rose to values 100-to 200-fold higher when biotin was co-injected with avidin as compared to streptavidin by two hours after injection. By that time, the V_D of the [H^3]-biotin in brain following co-injection

with avidin was more than five-fold greater than the V_D value observed when [H^3]-biotin was co-injected with streptavidin.

5 The calculations for the above findings involved plotting the ratio of the [H^3]-biotin organ V_D value after co-injection with avidin relative to the [H^3]-biotin organ V_D value following co-injection with streptavidin versus time after a single intravenous injection of the isotope in anesthetized rats. The findings indicated that avidin selectively delivered biotin to liver and kidney and, to a lesser extent, brain and heart relative to streptavidin as a vector.

10 The liver V_D value for a plasma marker, [H^3] rat serum albumin (RSA), for [I^{125}]-bio-SS-DDLVP co-injected with an excess of avidin, and for [I^{125}]-bio-SS-DDLVP co-injected with an excess of avidin following a thirty minute incubation with 25 mM dithiothreitol (DTT) were calculated. In the study leading to these calculations, the tail artery of the anesthetized rats was cannulated with PE-50 tubing and approximately 1 ml of arterial blood was collected over the five minute period following a rapid intravenous injection of isotope. The liver V_D value was computed by dividing the tissue radioactivity (DPM/g) by the integrated arterial serum radioactivity (DPM/ml). Thus, this external organ technique allowed for computation of organ V_D values using the integral of serum radioactivity obtained experimentally and was suitable for short timed experiments.

15 The serum radioactivity obtained five minutes after injection of [I^{125}]-bio-SS-DDLVP co-injected with avidin was applied to a Superose 12-HR fast protein liquid chromatography (FPLC) column, and the majority of the radioactivity eluted at 12 ml, which was identical to the elution volume of the [I^{125}]-avidin control. In contrast, the biotinylated [I^{125}]-DDLVP standard eluted at 16 ml. These data demonstrated that the majority of the biotinylated peptide was intact and bound to avidin during the experimental circulation.

20 The findings also demonstrated the marked increase in liver volume of distribution of [I^{125}]-bio-SS-DDLVP when the molecule was co-injected with avidin. For example, the 5-minute V_D of the DDLVP-avidin complex was more than seven-fold greater than the V_D of the co-injected [H^3]-rat serum albumin (RSA). The RSA distributes into the plasma space of the liver and represents the organ V_D value expected if there was no cellular uptake of the injected drug. RSA and avidin have essentially the same molecular weight (13). Therefore, the V_D value of RSA and DDLVP coupled to avidin should be identical in the absence of specific cellular uptake of the avidin complex. Conversely, when the [I^{125}]-bio-SS-DDLVP was treated with dithiothreitol (DTT) for 30 minutes prior to intravenous injection, the hepatic V_D decreased by more than two-thirds relative to the hepatic V_D values observed when there was no disulphide cleavage of the biotinylated DDLVP from the avidin vector.

25 In other studies, rat serum obtained two hours after an intravenous injection of [H^3]-biotin and streptavidin was eluted through the Superose 12-HR FPLC column and all [H^3]-radioactivity co-migrated with streptavidin, not free biotin. These studies reaffirmed previous demonstrations of the stability of the avidin-biotin bond in the circulation (18, 25).

30 The liver and kidney V_D values were determined with the external organ technique for a plasma marker [H^3]-RSA, for [P^{32}]-bio-DNA co-injected with avidin, and for [P^{32}]-bio-DNA co-injected with streptavidin. The data demonstrated that avidin selectively delivered the antisense oligonucleotide to liver and kidney *in vivo*, whereas streptavidin resulted in a distribution of the antisense oligonucleotide to these organs that is no greater than that of the RSA plasma marker, which has a molecular weight comparable to that of avidin. Serum obtained from these rats at the end of the circulation period was analyzed with a dextran-coated charcoal separation technique, which showed that more than 95% of the [P^{32}]-bio-DNA was bound by avidin in the circulation.

35 The liver and kidney V_D values for [H^3]-RSA or [P^{32}]-bio-antisense DNA co-injected with either avidin or streptavidin were determined. In both organs, the V_D value for the [P^{32}]-bio-antisense-DNA co-injected with either avidin or streptavidin were determined. In both organs, the V_D value for the [P^{32}]-bio-antisense-DNA co-injected with streptavidin was comparable to the V_D value of the plasma marker, [H^3]-RSA. Conversely, there was a five- to ten-fold increased tissue uptake of the [P^{32}]-bio-antisense DNA following co-injection with avidin.

40 *Example 2*

Polycationic Protein Inhibition of Avidin Vector Uptake

45 This study was performed to demonstrate inhibition of uptake of the avidin-biotin complex by isolated bovine brain capillaries caused by increasing concentrations of another polycationic protein, protamine. For this study, isolated brain capillaries were incubated with trace amounts of [H^3]- biotin that was stoichiometrically bound to 1 mg per ml medium avidin, and the uptake was inhibited 50% by 5 μ g per ml of protamine. The findings demonstrated that the absorptive-mediated endocytosis of the avidin-biotin complex by isolated bovine brain capillaries was a function of the polycationic nature of the avidin protein (16).

50 In other studies, the uptake of the avidin-biotin complex by isolated brain capillaries, used as an *in vitro* model system of blood-brain barrier transport, was shown to be time-dependent, temperature-dependent, and that the uptake was approximately 50% resistant to a mild acid wash assay used as a measurement of absorptive mediated endocytosis(16).

*Example 3*Avidin Protection of Biotinylated Antisense Oligonucleotide Against Degradation by Serum Exonuclease

5 The invention provides a method for protecting biotinylated antisense oligonucleotides from serum exonuclease degradation. The steps of this method are demonstrated in this example. The protocol and results are presented in Figs. 1a, 1b, and 1c.

10 Fig. 1a shows a 21-mer antisense oligonucleotide complementary to nucleotides 160-181 of the bovine GLUT-1 glucose transporter mRNA. This 21-mer was synthesized with an extended primary amine group by replacement of the deoxythymidine at position 20 with 6-amino-deoxyuridine, biotinylated with NHS-biotin and purified by the manufacturer (Genosys Biotechnologies, Inc., The Woodland, Texas). The oligonucleotide was labelled at the 5' end with [γ -P³²]-ATP using T₄ polynucleotide kinase to a specific activity of 1.1 microcuries/pmol. The labeled product was purified through Sephadex G-25 column. An aliquot of 12.8 pmol [P³²]-oligonucleotide was incubated with 140 μ g avidin in 100 μ l PBST (PBST = 10 millimolar phosphate buffer, pH 7.5; 0.15 M NaCl; 0.1% bovine serum albumin; 500 μ g tRNA/ml) at room temperature for 15 minutes. The avidin-[P³²]-oligonucleotide complex was purified by Sephadex G-75 column, prior to the experiment.

15 Fig. 1b shows the effect of avidin on the stability of biotinylated oligonucleotide in serum. In this aspect of the study, 4 μ l PBST containing 6 fmol [P³²]-oligonucleotide or [P³²]-oligonucleotide-avidin complex were incubated with PBST or rat serum (16 μ l) at 37° C for the time indicated in the Figure. The reaction was stopped by transferring tubes onto an ice bath and adding two volumes of 8 M urea-10% glycerol. Samples were heated 5 minutes at 95° C and incubated 5 minutes on ice immediately before resolving them in a 15% polyacrylamide-7 M urea sequencing gel. The autoradiogram of the gel is shown in Fig. 1b.

20 Fig. 1c shows a quantitation of the autoradiogram by laser scanning densitometry (LKB Model 2202 Ultrascan Laser Densitometer Bromma, Sweden). The results are expressed as percent 21-mer [P³²]-oligonucleotide X_n , [P³²]-oligonucleotides (degradation products). The labelled oligonucleotide is 80% 21-mer and 20% 20-mer [P³²]-oligonucleotide. Incubation of the unprotected (avidin-) [P³²]-oligonucleotide with serum (triangles) showed a rapid conversion to degradation products (20-and 19-mer) with a half-life ($t_{1/2}$) of approximately 13 minutes. On the other hand, incubation with avidin (avidin +) totally protected the [P³²]-oligonucleotide against degradation by the 3' exonuclease in serum during the incubation period.

30

*Example 4*AVIDIN FUSION PROTEIN VECTOR

35 This experiment was performed to demonstrate that avidin may be fused to a tissue-specific targeting moiety to form a tissue-specific transport vector comprising an avidin fusion protein. Such fusions can be achieved chemically, as in this example, or can be achieved genetically, as shown in Fig. 2.

40 The avidin fusion protein tissue-specific transport vector allows for specific targeting of any biotinylated peptide, drug, or antisense oligonucleotide. Furthermore, complex linker chemistry is eliminated by the method of the present invention for synthesizing avidin-fusion proteins comprising tissue-specific transport vectors.

45 In previous studies (29), cationized rat serum albumin has been shown to be a semi-brain specific transport vector, and to undergo absorptive-mediated endocytosis at brain capillaries *in vitro* and absorptive-mediated transcytosis across brain capillaries *in vivo* (29). The use of cationized rat albumin as a brain transport vector would normally necessitate complex linker chemistry involving the attachment of each individual drug to the cationized rat albumin transport vector. The method of the present invention, however, no longer requires complex linker chemistry to link cationized rat albumin to multiple drugs. The method of the present invention simply requires biotinylation of the various drug that may be coupled to the avidin fusion protein for drug delivery to the brain.

50 In this example, the uptake of [³H] by isolated bovine brain capillaries was shown to be nil in the presence of Ringer Hepes buffer or in the presence of buffer containing cationized rat albumin at a concentration of 150 nM. However, the uptake of the [³H] biotin was greatly facilitated by the addition of a cationized rat albumin/avidin conjugate at a concentration of 15 nM.

55 In other work, the uptake by isolated bovine brain capillaries of [P³²] biotinylated antisense oligonucleotide was measured after a 30 minute incubation of the isotope at either 4° C or 37° C in the presence of Ringer-Hepes buffer alone, cationized rat albumin (15 nM), or a cationized rat albumin/avidin conjugate 2.4 nM). The data was collected to reflect triplicate trials. The experiments showed that cationized rat albumin alone did not facilitate the uptake of the [P³²] biotinylated antisense oligonucleotide, but that the cationized rat albumin/avidin fusion protein did mediate the uptake of the biotinylated antisense oligonucleotide by brain capillaries, and that this process was impaired by incubation at low temperatures, consistent with absorptive-mediated endocytosis.

In this example, the cationized rat albumin/avidin fusion protein was prepared by coupling avidin to thiolated cationized rat albumin using m-maleimidobenzoyl-N-hydroxysuccinimide ester (MBS). The cationized rat albumin was thiolated with N-succinimidyl S-acetylthioacetate (SATA) and hydroxylamine. The MBS and SATA are standard coupling reagents and were purchased from Pierce Chemical Company, Rockford, IL.

5 Examples 1-4 provided *in vivo* and *in vitro* demonstrations that avidin-biotin technology of the present invention are appropriately applied to blood-brain barrier delivery of antisense oligonucleotides and peptides. In addition, the avidin-biotin technology of the present invention may also be employed to deliver antisense oligonucleotides or peptide pharmaceuticals to peripheral tissues, such as liver or kidney.

10 Although the present invention has been described in considerable detail with regard to certain preferred versions, other versions are possible. For example:

15 Vasopressin analogues are believed to be possible treatments for amnesia, but the successful use of these peptides in treatment of neurologic disorders has been limited by the poor transport of vasopressin across the blood-brain barrier. The DDLVP delivery to the brain using the avidin biotin technology described in Example 1 and 2 above may be used to transport the peptide across the blood-brain barrier. Alternatively, an avidin fusion protein, such as described in Example 4, above, may be used to transport DDLVP to brain, wherein the avidin fusion protein is comprised of avidin joined to a brain-specific transport vector.

20 Further, the antisense oligonucleotide used in Examples 1 and 2 above corresponds to the sequence flanking the methionine initiation codon of the GLUT-1 glucose transporter isoform mRNA. This gene is overexpressed in malignant tissues (28). The delivery of the antisense oligonucleotide to liver or kidney cancer using the compositions of the present invention may impair the production of the glucose transporter in the cancer cell, thus starving the malignant cell of the glucose energy source, resulting in malignant cell necrosis.

25 The present invention is also useful for delivery of antisense oligonucleotides to cultured cells *in vitro* in scaled up industrial level production of recombinant proteins. The composition of the invention can deliver to these cells antisense oligonucleotides that impair the production of proteases that degrade the recombinant protein being expressed in the transfected cultured cell. This would increase yield of the recombinant protein, e.g., insulin, and enhance industrial expression system by impairing the degradation of the recombinant protein.

30 In still another example, an antisense oligonucleotide selected for a viral-specific mRNA may be delivered to tissues using this technology for the purposes of treatment of the viral disease. Similarly, the delivery of an antisense oligonucleotide selected for a tumor-specific oncogene may be delivered for the treatment of a cancer. Similarly, a sense oligonucleotide that binds a cytosolic mRNA stability factor may be delivered to tissues for the purpose of increasing the degradation of tumor-specific mRNA.

35 The avidin-biotin technology may also be used in the diagnosis of disorders using standard imaging technology such as positron emission tomography or single photon computer emission tomography. For example, a radio-labelled cholecystokinin (CCK) peptide may be delivered to brain using the present invention for the purpose of imaging CCK-specific receptors in the diagnosis of mental disorders. Conversely, a radio-labeled antisense oligonucleotide may be delivered to tissues for the purpose of imaging cancer or viral disorders.

Claims

1. A composition for delivery of an agent to cells, said composition comprising:

25 a transport vector comprising an avidin moiety chosen from avidin tetramer, avidin monomer subunit, avidin dimer subunit, and non-glycosylated derivatives thereof; at least one monobiotinylated agent bonded to said avidin moiety via an avidin-biotin linkage to provide an avidin-biotin-agent complex.

2. A composition according to claim 1 further comprising a pharmaceutically acceptable carrier for said avidin-biotin-agent complex.

3. A composition according to claim 1 or 2 wherein the biotinylated agent comprises a pharmaceutical compound chosen from peptides, antisense oligonucleotides, immunoglobulins, and organic chemicals.

35 4. A composition according to claim 1 and wherein the monobiotinylated agent comprises a diagnostic compound chosen from immunoglobulins, oligonucleotides, amyloid ligands, and receptor ligands.

5. A composition according to any preceding claim wherein said avidin moiety comprises a dimer of avidin.

40 6. A composition according to any preceding claim wherein said transport vector further includes a targeting moiety bound to said avidin moiety, said targeting moiety providing transport of said avidin-biotin-agent complex to specific cells.

45 7. A composition according to claim 6 wherein said targeting moiety is chosen from immunoglobulins, receptor ligands, cationized proteins, and lectins.

8. A composition according to claim 6 wherein said transport vector is a fusion polypeptide produced from a fused gene, said fused gene being a nucleotide sequence encoding said fusion polypeptide, said nucleotide sequence comprised of a nucleotide sequence encoding said avidin moiety fused to a nucleotide sequence encoding said targeting moiety.

50 9. A composition according to claim 8 wherein said avidin moiety is the dimer form.

55 10. The composition of claim 7 wherein said avidin moiety is linked at the F_c region of an immunoglobulin.

11. A composition according to any preceding claim, wherein the monobiotinylated agent is chosen from biotinylated oligonucleotides, polypeptides, immunoglobulins, and organic chemicals.

12. A composition according to claim 11 wherein the monobiotinylated agent moiety comprises an oligonucleotide.
13. A composition according to claim 12 wherein said monobiotinylated oligonucleotide is monobiotinylated toward the 3' end of said oligonucleotide.
- 5 14. A composition according to claim 12 or 13 wherein the oligonucleotide is an antisense oligonucleotide.
15. A composition according to any preceding claim for use in delivering an agent to cells wherein said cells comprise tissues and organs *in vivo*.
- 10 16. A composition according to claim 15 wherein said tissues and organs include brain, liver, kidney, and heart.
17. A composition according to claims 15 or 16 wherein delivering comprises administering said composition to an individual.
- 15 18. A pharmaceutical composition comprising the composition of any of claims 1 to 14 in a pharmaceutically acceptable carrier.
- 20 19. A pharmaceutical composition according to claim 18 for use in a therapeutic treatment of a subject which comprises administering a therapeutic dosage to the subject.
- 20 20. A composition according to claim 19 wherein said therapeutic dosage is from about 0.001 mg/kg to about 1 mg/kg.
- 25 21. A composition according to any of claims 1 to 14 for use in a diagnostic treatment.
22. A DNA sequence encoding the fusion polypeptide of claim 8.
- 25 23. A recombinant host cell containing the DNA sequence of claim 22, wherein said recombinant host cell produces said fusion polypeptide in sufficient quantity for substantial isolation and purification of said fusion polypeptide.
- 30 24. A composition comprising a fusion protein produced by the recombinant host cell of claim 23.
- 25 25. A method for delivering an agent to cells *in vitro* comprising the steps of:
 - 35 (a) providing a composition which includes
 - i. a transport vector including an avidin moiety chosen from avidin tetramer, avidin monomer subunit, avidin dimer subunit, and non-glycosylated derivatives thereof, and
 - ii. at least one monobiotinylated agent bonded to said avidin moiety via an avidin-biotin linkage to provide an avidin-biotin agent complex,
 - 40 (b) contacting said cells with said composition *in vitro*.
26. A method according to claim 25 wherein said transport vector further includes a targeting moiety bound to said avidin moiety, said targeting moiety providing transport of said avidin-biotin-agent complex to specific cells.
- 45 27. A method for synthesizing a composition according to any of claims 1 to 14 comprising the steps of:
 - 50 (a) forming a transport vector comprising an avidin moiety chosen from avidin tetramer, avidin monomer subunit, avidin dimer subunit, and non-glycosylated derivatives thereof;
 - (b) forming a monobiotinylated agent;
 - (c) bonding said transport vector to said monobiotinylated agent via an avidin-biotin linkage to provide an avidin-biotin-agent complex.
- 55 28. A method according to claim 27 wherein said transport vector further includes a targeting moiety bound to said avidin moiety.
29. A method according to claim 27 or 28 wherein said transport vector is produced by recombinant means.

30. A method for protecting oligonucleotides from 3' exonuclease degradation comprising the steps of:
 monobiotinylating said oligonucleotid to form a monobiotinylated oligonucleotide, the site of biotinylation being toward the 3' end of the oligonucleotide;
 reacting said monobiotinylated oligonucleotide with an avidin moiety to form an avidin-biotin-oligonucleotide complex.

5

Patentansprüche

1. Zusammensetzung zur Zuführung eines Mittels an Zellen, wobei die Zusammensetzung umfaßt:
 10 einen Transportvektor, umfassend einen Avidinrest, gewählt aus Avidin-Tetramer, Avidin-Monomeruntereinheit, Avidin-Dimeruntereinheit und nicht-glycosylierten Derivaten davon; mindestens ein monobiotinyliertes Mittel, welches an den Avidinrest über eine Avidin-Biotin-Verknüpfung gebunden ist, um einen Avidin-Biotin-Mittel-Komplex bereitzustellen
- 15 2. Zusammensetzung nach Anspruch 1, ferner umfassend einen pharmazeutisch annehmbaren Träger für den Avidin-Biotin-Mittel-Komplex.
3. Zusammensetzung nach Anspruch 1 oder 2, worin das biotinylierte Mittel eine pharmazeutische Verbindung umfaßt, gewählt aus Peptiden, Antisinn-Oligonucleotiden, Immunoglobulinen und organischen Chemikalien.
- 20 4. Zusammensetzung nach Anspruch 1 und wobei das monobiotinylierte Mittel eine diagnostische Verbindung umfaßt, gewählt aus Immunoglobulinen, Oligonucleotiden, Amyloidliganden und Rezeptorliganden.
5. Zusammensetzung nach mindestens einem vorstehenden Anspruch, worin der Avidinrest ein Dimer von Avidin umfaßt.
- 25 6. Zusammensetzung nach mindestens einem vorstehenden Anspruch, worin der Transportvektor ferner einen Zielmarken- bzw. Targeting-Rest umfaßt, der an den Avidinrest gebunden ist, wobei der Targeting-Rest den Transport des Avidin-Biotin-Mittel-Komplexes zu spezifischen Zellen ermöglicht.
- 30 7. Zusammensetzung nach Anspruch 6, worin der Targeting-Rest aus Immunoglobulinen, Rezeptorliganden, kationisch gemachten Proteinen und Lectinen gewählt wird.
8. Zusammensetzung nach Anspruch 6, worin der Transportvektor ein von einem Fusionsgen hergestelltes Fusionspolypeptid ist, wobei das Fusionsgen eine für das Fusionspolypeptid codierende Nucleotidsequenz ist, wobei die Nucleotidsequenz aus einer Nucleotidsequenz besteht, welche für den Avidinrest in Fusion mit einer für den Targeting-Rest codierende Nucleotidsequenz codiert.
- 35 9. Zusammensetzung nach Anspruch 8, worin der Avidinrest in der Dimer-Form vorliegt.
- 40 10. Zusammensetzung von Anspruch 7, worin der Avidinrest an die F_c-Region eines Immunoglobulins gebunden ist.
11. Zusammensetzung nach mindestens einem vorstehenden Anspruch, worin das monobiotinylierte Mittel aus biotinierten Oligonucleotiden, Polypeptiden, Immunoglobulinen und organischen Chemikalien gewählt wird.
- 45 12. Zusammensetzung nach Anspruch 11, worin der monobiotinylierte Mittel-Rest ein Oligonucleotid umfaßt.
13. Zusammensetzung nach Anspruch 12, worin das monobiotinylierte Oligonucleotid gegen das 3'-Ende des Oligonucleotids hin monobiotinyliert ist.
- 50 14. Zusammensetzung nach Anspruch 12 oder 13, worin das Oligonucleotid ein Antisinn-Oligonucleotid ist.
15. Zusammensetzung nach mindestens einem vorstehenden Anspruch zur Verwendung bei der Zuführung eines Mittels an Zellen, worin die Zellen Gewebe und Organe *in vivo* umfassen.
- 55 16. Zusammensetzung nach Anspruch 15, worin die Gewebe und Organe Gehirn, Leber, Niere und Herz einschließen.
17. Zusammensetzung den Ansprüchen 15 oder 16, worin die Zuführung das Verabreichen der Zusammensetzung an ein Individuum umfaßt.

18. Pharmazeutische Zusammensetzung, umfassend die Zusammensetzung von mindestens einem der Ansprüche 1 bis 14 in einem pharmazeutisch annehmbaren Träger.
19. Pharmazeutische Zusammensetzung nach Anspruch 18 zur Verwendung bei einer therapeutischen Behandlung eines Subjekts, welche die Verabreichung einer therapeutischen Dosis an das Subjekt umfaßt.
20. Zusammensetzung nach Anspruch 19, worin die therapeutische Dosis etwa 0,001 mg/kg bis etwa 1 mg/kg beträgt.
21. Zusammensetzung nach mindestens einem der Ansprüche 1 bis 14 zur Verwendung bei einer diagnostischen Behandlung.
22. DNA-Sequenz, welche für das Fusionspolypeptid von Anspruch 8 codiert.
23. Rekombinante Wirtszelle, enthaltend die DNA-Sequenz von Anspruch 22, wobei die rekombinante Wirtszelle das Fusionspolypeptid in ausreichender Menge für eine wesentliche Isolierung und Reinigung des Fusionspolypeptids herstellt.
24. Zusammensetzung, umfassend ein Fusionsprotein, das von der rekombinanten Wirtszelle von Anspruch 23 hergestellt wird.
25. Verfahren zur Zuführung eines Mittels an Zellen *in vitro*, umfassend die folgenden Schritte:
 - (a) Vorsehen einer Zusammensetzung, welche folgendes einschließt
 - i. einen Transportvektor, einschließlich einen Avidinrest, gewählt aus Avidin-Tetramer, Avidin-Monomeruntereinheit, Avidin-Dimeruntereinheit und nicht-glycosylierten Derivaten davon, und
 - ii. mindestens ein monobiotinyliertes Mittel, das an den Avidinrest über eine Avidin-Biotin-Verknüpfung gebunden ist, um einen Avidin-Biotin-Mittel-Komplex bereitzustellen,
 - (b) Kontaktieren der Zellen mit der Zusammensetzung *in vitro*.
26. Verfahren nach Anspruch 25, worin der Transportvektor ferner einen an den Avidinrest gebundenen Targeting-Rest einschließt, wobei der Targeting-Rest den Transport des Avidin-Biotin-Mittel-Komplexes zu spezifischen Zellen ermöglicht.
27. Verfahren zur Synthese einer Zusammensetzung nach mindestens einem der Ansprüche 1 bis 14, umfassend die folgenden Schritte:
 - (a) Bilden eines Transportvektors, umfassend einen Avidinrest, gewählt aus Avidin-Tetramer, Avidin-Monomeruntereinheit, Avidin-Dimeruntereinheit und nicht-glycosylierten Derivaten davon;
 - (b) Bilden eines monobiotinylierten Mittels;
 - (c) Binden des Transportvektors an das monobiotinylierte Mittel über eine Avidin-Biotin-Verknüpfung, um einen Avidin-Biotin-Mittel-Komplex bereitzustellen.
28. Verfahren nach Anspruch 27, worin der Transportvektor ferner einen an den Avidinrest gebundenen Targeting-Rest einschließt.
29. Verfahren nach Anspruch 27 oder 28, worin der Transportvektor auf rekombinantem Wege hergestellt wird.
30. Verfahren zum Schutz von Oligonucleotiden vor 3'-Exonucleaseabbau, umfassend die folgenden Schritte:
 - Monobiotinylieren des Oligonucleotids unter Bildung eines monobiotinylierten Oligonucleotids, wobei die Stelle der Biotinylierung gegen das 3'-Ende des Oligonucleotids hin liegt;
 - Umsetzen des monobiotinylierten Oligonucleotids mit einem Avidinrest, um einen Avidin-Biotin-Mittel-Komplex zu bilden.

Revendications

1. Composition qui permet d'apporter un agent à des cellules, et qui comprend :
5 un transporteur qui comporte une entité de type avidine, choisie parmi l'avidine tétramère, la sous-unité monomère de l'avidine, la sous-unité dimère de l'avidine et leurs dérivés non-glycosylés, et au moins un agent monobiotinylé et lié à l'entité de type avidine par un enchaînement avidine-biotine pour former un complexe avidine-biotine-agent.
2. Composition conforme à la revendication 1, qui comprend en outre un véhicule, admissible en pharmacie, pour le 10 complexe avidine-biotine-agent.
3. Composition conforme à la revendication 1 ou 2, dans laquelle l'agent biotinylé comporte un composé pharmaceutique choisi parmi les peptides, les oligonucléotides antisens, les immunoglobulines et les composés chimiques 15 organiques.
4. Composition conforme à la revendication 1, dans laquelle l'agent monobiotinylé comporte un composé diagnostique choisi parmi les immunoglobulines, les oligonucléotides, les ligands pour dépôts amyloïdes et les ligands pour récepteurs. 20
5. Composition conforme à l'une des revendications précédentes, dans laquelle l'entité de type avidine est la sous-unité dimère d'avidine.
6. Composition conforme à l'une des revendications précédentes, dans laquelle l'edit transporteur comporte en outre 25 une entité de ciblage qui est liée à l'entité de type avidine et qui assure le transport du complexe avidine-biotine-agent vers des cellules particulières.
7. Composition conforme à la revendication 6, dans laquelle l'entité de ciblage est choisie parmi les immunoglobulines, les ligands pour récepteurs, les protéines rendues cationiques et les lectines. 30
8. Composition conforme à la revendication 6, dans laquelle le transporteur est un polypeptide de fusion produit par un assemblage de gènes constituant une séquence de nucléotides qui code ce polypeptide de fusion et qui comporte une séquence de nucléotides codant l'entité de type avidine, assemblée avec une séquence de nucléotides codant l'entité de ciblage. 35
9. Composition conforme à la revendication 8, dans laquelle l'entité de type avidine est la sous-unité dimère.
10. Composition conforme à la revendication 7, dans laquelle l'entité de type avidine est liée au domaine F_c d'une immunoglobuline. 40
11. Composition conforme à l'une des revendications précédentes, dans laquelle l'agent monobiotinylé est choisi parmi les oligonucléotides, polypeptides, immunoglobulines et composés chimiques organiques biotinylés.
12. Composition conforme à la revendication 11, dans laquelle l'agent monobiotinylé est un oligonucléotide. 45
13. Composition conforme à la revendication 12, dans laquelle le site de biotinylation de l'oligonucléotide monobiotinylé se situe au voisinage de l'extrémité 3'-terminale de l'oligonucléotide.
14. Composition conforme à la revendication 12 ou 13, dans laquelle l'oligonucléotide est un oligonucléotide antisens. 50
15. Composition conforme à l'une des revendications précédentes, destinée à être utilisée pour apporter *in vivo* un agent à des cellules constituant des tissus ou des organes.
16. Composition conforme à la revendication 15, dans laquelle les tissus ou organes sont le cerveau, le foie, le rein ou le cœur. 55
17. Composition conforme à la revendication 15 ou 16, l'opération d'apport consistant à administrer la composition à un patient.

18. Composition pharmaceutique comprenant une composition conforme à l'une des revendications 1 à 14, mise dans un véhicule admissible en pharmacie .
19. Composition pharmaceutique conforme à la revendication 18, destinée à être utilisée pour le traitement thérapeutique d'un patient, lequel traitement consiste à administrer au patient une dose thérapeutique de cette composition.
20. Composition conforme à la revendication 19, dont la dose thérapeutique vaut d'environ 0,001 mg/kg à environ 1 mg/kg.
21. Composition conforme à l'une des revendications 1 à 14, destinée à être utilisée pour un traitement diagnostique.
22. Séquence d'ADN codant un polypeptide de fusion défini dans la revendication 8.
23. Cellule-hôte de recombinaison, qui renferme une séquence d'ADN conforme à la revendication 22 et qui produit ludit polypeptide de fusion en une quantité suffisante pour que l'on puisse effectivement isoler et purifier ce polypeptide de fusion.
24. Composition comprenant une protéine de fusion produite par une cellule-hôte de recombinaison conforme à la revendication 23.
25. Procédé permettant d'apporter *in vitro* un agent à des cellules et comportant les étapes consistant à :
 - a) se procurer une composition qui contient
 - i) un transporteur qui comporte une entité de type avidine, choisie parmi l'avidine tétramère, la sous-unité monomère de l'avidine, la sous-unité dimère de l'avidine et leurs dérivés non-glycosylés, et
 - ii) au moins un agent monobiotinylé et lié à l'entité de type avidine par un enchaînement avidine-biotine pour former un complexe avidine-biotine-agent, et
 - b) mettre *in vitro* cette composition en contact avec les cellules.
26. Procédé conforme à la revendication 25, dans lequel le transporteur comporte en outre une entité de ciblage qui est liée à l'entité de type avidine et qui assure le transport du complexe avidine-biotine-agent vers des cellules particulières.
27. Procédé de synthèse d'une composition conforme à l'une des revendications 1 à 14, qui comporte les étapes consistant à :
 - a) former un transporteur qui comporte une entité de type avidine, choisie parmi l'avidine tétramère, la sous-unité monomère de l'avidine, la sous-unité dimère de l'avidine et leurs dérivés non-glycosylés,
 - b) former un agent monobiotinylé, et
 - c) lier le transporteur à l'agent monobiotinylé, par un enchaînement avidine-biotine, pour former un complexe avidine-biotine-agent.
28. Procédé conforme à la revendication 27, dans lequel le transporteur comporte en outre une entité de ciblage qui est liée à l'entité de type avidine.
29. Procédé conforme à la revendication 27 ou 28, dans lequel le transporteur est obtenu par recombinaison génétique.
30. Procédé permettant de protéger des oligonucléotides contre la dégradation provoquée par une 3'-exonucléase, qui comporte les étapes consistant à :
 - monobiotinyler l'oligonucléotide pour former un oligonucléotide monobiotinylé dont le site de biotinylation se situe au voisinage de l'extrémité 3'-terminale de l'oligonucléotide, et
 - faire réagir cet oligonucléotide monobiotinylé avec une entité de type avidine, pour former un complexe avidine-biotine-oligonucléotide.
